Comparison of the effect of three methods of using topical lidocaine gel into cervix, intrauterine infusion of lidocaine and combination of them on reducing the pain during curettage.

Protocol summary

Summary

Objectives: this study compares the efficacy of the intracervical application of lidocaine gel, the intrauterine infusion of lidocaine, and the co-administration of these procedures in alleviating pain during curettage. **Design:** it was a unicentric, randomized, and unblinded study. **Population:** pregnant women (n=120) with a dilated cervix, in the 8th-13th week of pregnancy and hospitalized in Kowsar Hospital in Qazvin participated in the study. **Inclusion and exclusion criteria:** being in the 8th-13th week of pregnancy and having a dilated cervix were the inclusion criteria. Using an analgesic 24 hours before curettage and having genital infections, severe uterine bleeding, drug addiction, and a history of allergy to lidocaine were set as the exclusion criteria. **Setting:** the subjects were assigned to three groups. Group 1 received an intrauterine lidocaine infusion and intracervical lidocaine gel. An intrauterine lidocaine infusion and placebo gel were administered to the second group. Group 3 received intracervical lidocaine gel and an intrauterine infusion of normal saline. **Interventions:** in the first group, 5 cc of 2% lidocaine was intrauterinely infused and 3 cc of the lidocaine gel was applied over the cervix. In the second group, 5 cc of 2% lidocaine was intrauterinely infused and 3 cc of the placebo gel was applied over the cervix. In the third group, 5 cc of normal saline was intrauterinely infused and 3 cc of the lidocaine gel was applied over the cervix. **Primary outcome variables:** exploring the effectiveness of local analgesia during curettage and obviating the need for general anesthesia.
