Effect of Physical Activity on Static and Dynamic Balance among the Elderly

Protocol summary

Study aim

: with advancing age, and the impact of age-related chronic diseases, a decline in balance as a cognitive capability function is also observed. Therefore, this study aimed to investigate the effect of physical activity on the static and dynamic balance of the elderly living in the nursing home

Design

: In this study, 36 healthy subjects with no history of regular exercise (71.8 ± 5.6 years old and body mass index 23.4 ± 6.8) were selected by convenient sampling. After obtaining informed written consent and the physician permission, qualified subjects were enrolled in the study and were examined before and after physical exercise. To evaluate dynamic and static balance of the subjects, we used TUG and Sharpend-Romberg tests. The exercises were progressively implemented for 8 weeks and 3 hours per week. To analyze the data, appropriate statistical tests at the significant level of $P < 0.05$ and SPSS version 20 were used.

Settings and conduct

After the physical activity was completed, the eligible elderly were visited by a physician at the nursing home and obtained a permission to participate in the research. Finally, written informed consent was obtained from the subjects for participation in the study. After initial tests and physician permission, 41 elderly (26 women, 15 men) declared their readiness to participate in the research. Initially, all subjects were evaluated by a tool for measuring static and dynamic balance measurements and data obtained were recorded. The elderly were trained for 8 weeks and 3 sessions per week in group. Sampling was carried out in December 2016 and January 2017.

Participants/Inclusion and exclusion criteria

Prior to entering the program, the elderly were evaluated for physical activity using a physical activity readiness questionnaire. According to this questionnaire, elderly patients with history of heart disease, hypertension,

physician's order for non-doing exercise or workout, nerve dysfunction, dizziness, eye and ear diseases (other than presbyopia and presbycusis), previous fractures of the involved bones in the balance (femur, tibia and fibula) and the BMI greater than 36, the absence of more than 3 sessions in the exercise were excluded from the study

Intervention groups

his is a quasi-experimental study in which 36 elderly people in the age range of 60 to 85 years (age 71.6 ± 5.6), body mass index (23.4 ± 6.8), residence for more than 3 months in the nursing home of Sabzevar and without a history of falling were investigated through a pre-test and post-test comparisons

Main outcome variables

, the presence of nurses with the elderly and sometimes living with them has made it more tangible for nurses to take a step for providing preventive care. In this study, we sought to demonstrate that by offering proper physical exercises and simple and low cost sports equipment, caring nurses at home or nursing home can take steps to prevent falls and increase the balance of the elderly. Using exercises at home or nursing home can reduce the level of falling among the elderly and prevent further complications in them.

Scientific title

Effect of Physical Activity on Static and Dynamic Balance among the Elderly

Public title

Effect of Physical Activity on Static and Dynamic Balance among the Elderly

Purpose

Prevention

Inclusion/Exclusion criteria**Inclusion criteria:**

Aged between 60 and 85 years old • were living in Sabzevar seniors' homesteads • have lived in the center for more than three months • obtained a full grade score by completing the test for physical activity (answered all questions) . • No history of falling or falling down. • Body mass index below 35.

Exclusion criteria:

During the study, the researcher will find that he or she will be on regular basis for the day. • The research sample will fall during the study. • The research sample during the study due to an ear infection will be impaired in the balance of the individual. • There are no more than three consecutive sessions in the physical training session. • More than 6 absent training sessions.

Other design features

After the initial tests and the doctor's permission, 32 elderly people will be satisfied to participate in the research. Initially, all subjects will be evaluated by means of a static equilibrium and dynamic equilibrium measuring instrument, and the information will be recorded. Seniors are practicing in groups for 8 weeks and 3 sessions a week. Sampling will be carried out in two consecutive months. Also, the implementation of all examinations and exercises will be carried out by direct supervision of the Master of Physical Education. During the research phase, subjects who are excluded from the study will be excluded from the study. The training will be conducted for 40 minutes in the first 4 weeks of the week and 1 hour in the final week. To ease the exercise and focus more elderly, the subjects will be divided into 5 groups of 6 to 8 groups. In order to influence the training of time, the intensity of exercises, the stimulation of effective balance sensations, such as sight and deep tendon, and hemodynamic symptoms during the intervention, will gradually increase. At the end of the intervention, all subjects will be subjected to static and dynamic equilibrium tests. And the average results before and after the comparison and conclusion.
