Study the effect of intraperitoneal bupivacaine on patient's pain relief after laparoscopic cholecystectomy

Protocol summary

Summary

This was a double blind randomized clinical trial which performed on 66 patients, ASA I, II who were candidate for laparoscopic cholecystectomy in Imam Reza Hospital, Kermanshah, Iran. The age of patients ranged 20-60 years. Patients with history of Diabetes, acute cholecystitis, heart ischemia, former bile ducts surgeries, addiction and sensitivity to local anesthesia drugs were excluded from the study. Patients were divided to two groups: target group and control group. Both groups received the same anesthesia method. Patients in target group were injected 20cc bupivacaine 0.25% (20cc vial, Merc Inc) in diaphragm right cavity at the beginning and at the end of operation but control group had no injection. Patients in both groups received 5cc bupivacaine 0.25% through all their incisions on the abdomen, it was the unique point of our study which made it different from all other studies. Patients' pain was assessed by VAS in both two groups every 1 hour for 4 hours after transferring to ward. Their nausea severity was assessed by VAS method too.
