The efficacy of combination of behavioural activation and drug treatment therapies in depressed inpatients

Protocol summary

Summary

This is a randomized controlled trial. The aim of the trial was to assess the efficacy of combination of behavioural activation and drug treatment therapies in depressed inpatients. For this purpose we compared three intervention groups including: Behavioral activation group receiving behavioral activation + drug treatment; Movie group participating in sessions to watch movies instead of behavioural activation to neutralize the therapist's effect + drug treatment; and Control group with no behavioral intervention receiving only drug treatment. 24 depressed inpatients were recruited. Inclusion criteria: Minimum guidance school education (total educational years of at least 8 years), age between 20 and 50, diagnosis of depression. Exclusion criteria: Having the features of psychosis, be a candidate for electroconvulsive therapy, having suicidal thoughts. Level of depression was assessed before and after intervention in each patient. The measurements were repeated 2 month after intervention as well. The Beck Depression inventory was used to measure depression. The results were compared in the three groups.
