Comparison of rotational and elevatory resistive exercises on acromiohumeral distance in people with shoulder impingement syndrome: A randomized clinical trial

Protocol summary

Study aim

Comparison of the effect of rotational and elevatory resistance exercises on acromiohumeral distance in patients with shoulder impingement syndrome

Design

54 patients with shoulder impingement syndrome are randomly divided into 3 groups. The study is a randomized clinical trial. The Stratified Permuted Block Randomization method is used for randomization. The two intervention groups receive exercise therapy and the third group is considered as the control group. Acromiohumeral distance measurement is done once before the intervention and once after the intervention.

Settings and conduct

This study is performed at the neuromuscular Rehabilitation Research Center. Patients are invited to participate in the study based on their physician's diagnosis

Participants/Inclusion and exclusion criteria

Inclusion criteria: 1. Aged 17 to 35 years 2. History of pain in anterior and lateral of the upper shoulder that has lasted more than a week in the last six months 3. Having at least three of the following: Positive Neer test - Positive Hawkins Kennedy test - Positive Job test - Painful arch during flexion and abduction movements - Pain during resisted lateral rotation and / or resisted abduction Exclusion criteria: Body mass index (BMI) above 25 kg/m². Complete rupture of the rotator cuff. Moderate to severe glenohumeral or acromioclavicular joint osteoarthritis. Glenohumeral joint instability including previous dislocation or subluxation. Previous shoulder fracture

Intervention groups

The intervention of the first group is rotational resistance exercises and the intervention of the second group is elevatory resistance exercises. The control group does not receive any intervention and is only evaluated.

Main outcome variables

Measurement of acromiohumeral distance

Scientific title
Comparison of rotational and elevatory resistive exercises on acromiohumeral distance in people with shoulder impingement syndrome: A randomized clinical trial

Public title
The effect of rotational and elevatory resistive exercises on acromiohumeral distance in patients with shoulder impingement syndrome

Purpose
Treatment

Inclusion/Exclusion criteria
Inclusion criteria:
Aged 17 to 35 years History of pain in anterior and lateral of the upper shoulder that has lasted more than a week in the last six months Having at least three of the following: Positive Neer test ;Positive Hawkins-kennedy test ;Positive Job test ;Painful arch during flexion and abduction movements ;Pain during resisted lateral rotation and / or resisted abduction
Exclusion criteria:
Body mass index (BMI) above 25 kg/m2. Complete rupture of the rotator cuff Moderate to severe glenohumeral or acromioclavicular joint osteoarthritis Glenohumeral joint instability including previous dislocation or subluxation Previous shoulder fracture Neurological defect of the upper limb Systemic diseases such as rheumatoid arthritis Neck pain with somatic or radicular pain pattern Previous history of shoulder surgery Corticosteroid injection in the shoulder during the last month Loss of range of motion of the shoulder joint (for example due to adhesions) Malignancy and hemophilia Deformity in the shoulder Osteoporosis Any history of damage to the brachial plexus Any subcutaneous inflammation

Age
From **17 years** old to **35 years** old

Gender
Both

Phase
N/A

Groups that have been masked
No information

Sample size
Target sample size: **54**

Randomization (investigator's opinion)
Randomized

Randomization description
Samples are randomly assigned using the Stratified Permuted Block Randomization method with 6 9 blocks assigned to three groups. In this method, A will represent group one (rotational resistance exercises), B will represent group two (elevatory resistance exercises) and C will represent the control group. In this way, the order of interventions A, B and C in the form of blocks from 1 to 6 is determined by the methodological consultant of the project, and is provided to the executive supervisor

of the project, and the researcher obtains an assignment from the executive supervisor to assign each qualified person. Slowly The supervisor first selects the block using a random number generator (or dice) and then the eligible individuals are assigned to one of three groups A, B or C in a predetermined order. It should be noted that if a block is selected based on random numbers that have already filled all 9 sequences, another random number will be selected again for that person.

Blinding (investigator's opinion)

Intervention groups

1

Description

Intervention group 1: Rotational shoulder resistance exercises are performed three times a week for 6 consecutive weeks, including 1) The patient is placed in a sitting position on a chair and the therapist stands on the affected side and the patient's elbow is placed at 90 degrees flexion. The patient moves the internal rotation of the arm from the end of the external rotation range to the end of the internal rotation range against the therapist's resistance. In order to prevent compensatory movements in the shoulder, the therapist holds the patient's elbow steady with one hand and applies resistance with the other hand on the end of the patient's forearm. The patient stands and elbows are placed at 90 degrees of flexion. The patient moves the external rotation of the arm from the end of the internal rotation range to the end of the external rotation range against the therapist's resistance. In order to prevent compensatory movements in the shoulder, the therapist holds the patient's elbow with one hand and applies resistance with the other hand on the end of the patient's forearm. 3) The patient is placed in a sitting position and the therapist is on the affected side Stand and elbow at 90 degrees flexion. The patient is asked to place the shoulder at angles of 30, 90, and 150 degrees around the scapula, and then the therapist applies force to the end of the patient's forearm to create internal rotation and external rotation of the arm, and the patient is asked to contract. Keep the shoulder isometric in the same position. In order to prevent compensatory movements in the shoulder, the therapist holds the patient's elbow with his hand.

Description

Intervention group 2: elevatory shoulder resistance exercises are performed three sessions per week for 6 consecutive weeks, including 1) the patient is sitting on a chair and the therapist is standing on the affected side. The elbow is slightly bent at the flexion and thumb to create an external rotation in the arm facing the ceiling. The patient is then asked to move his or her process on the scapula to an angle of 150 degrees against resistance by the therapist. In order to apply the resistance force, the therapist's hand is placed on the end of the patient's forearm. 2) The patient is placed in a sitting position and the therapist stands on the affected side. The elbow is slightly bent at the flexion and thumb

to create an external rotation in the arm facing the ceiling. The patient is asked to place the shoulder at 30, 90, and 150 degrees of rotation at the scapula, and then the therapist randomly applies force to the patient's forearm to raise and lower the patient's shoulder, and the patient is asked to contract. Maintain the isometric shoulder in the same position.
