Investigating effects of extracorporeal shockwave therapy on hamstring tightness and comparing it with dynamic soft tissue mobilization in basketball players aged 15 to 18 years old

Protocol summary

Study aim

Determining and comparing the effect of extracorporeal shock wave and dynamic soft tissue mobilization on hamstring tightness in basketball players

Design

Non-randomized, Single-blinding clinical trial, with the parallel groups, Phase 2 on 40 patients

Settings and conduct

In this randomized, single-blind clinical trial, 40 eligible basketball players referred to Amin hospital in Isfahan will be included in the study and will be divided into two groups. Participants in the first group will be treated with mobilization and in the second group will be treated with extracorporeal shockwave. Then the active knee extension angle, Y balance test and popliteal angle will be evaluated and compared between the two groups.

Participants/Inclusion and exclusion criteria

Inclusion criteria included basketball players with hamstring tightness or limited active knee extension angle (AKEA), in the age group of 15 to 18 years, with at least two years of playing basketball and at least 3 sessions per week. Exclusion criteria include a positive slump test, having a history of hip and knee fractures, having a history of femoral fracture, existence of internal fixators such as screws and plates, acute hamstring injury, having a history of back pain in the last three months, complaints of pain and injury to the knee and hip joints, tightness in the knee joint, having a coagulation disorder / acute infection / pregnancy / malignancy.

Intervention groups

Intervention group 1: In this group, participants will undergo dynamic soft tissue mobilization by an experienced physiotherapist for 4 weeks, three sessions per week. Intervention group 2: In this group, participants will be extracorporeal shock wave for 4 weeks, one session per week.

Main outcome variables

Active knee extension angle; Performance and balance; Popliteal angle

Scientific title

Investigating effects of extracorporeal shockwave therapy on hamstring tightness and comparing it with dynamic soft tissue mobilization in basketball players aged 15 to 18 years old

Public title

Investigating effects of extracorporeal shockwave therapy on hamstring tightness and comparing it with dynamic soft tissue mobilization in basketball players

Purpose

Treatment

Inclusion/Exclusion criteria**Inclusion criteria:**

Age between 15 to 18 years Having at least two years of playing basketball and at least 3 sessions per week Referral with the main complaint of posterior femoral hamstring tightness or limitation of the active knee extension angle (AKEA) below 170 degrees of knee extension Consent to participate in the study

Exclusion criteria:

Positive slump test The history of hip and knee fractures The history of femoral bone fracture Existence of internal fixators such as screws and plates Acute hamstring injury The history of back pain in the last three months Complaints of pain and injury to the knee and hip joints Tightness in the knee joint The coagulation disorder / acute infection / pregnancy / malignancy

Age

From **15 years** old to **18 years** old

Gender

Both

Phase

2

Groups that have been masked

- Participant
- Outcome assessor
- Data analyser
- Data and Safety Monitoring Board

Sample size

Target sample size: **40**

Randomization (investigator's opinion)

Randomized

Randomization description

Due to the fact that patients are added to the study over time and not all cases are available at the same time, in order to perform randomization, each eligible patient is assigned to one of the two groups by lottery.

Blinding (investigator's opinion)

Single blinded

Blinding description

Due to the difference in intervention in each of the two groups, the investigator are aware of the type of intervention in each group. But the participant, the outcome assessor, and the Data analyser will not have any knowledge of the type of intervention in each group.

Immediately and one month after the intervention

Method of measurement

3**Description**

Performance and balance

Timepoint

Immediately and one month after the intervention

Method of measurement

Y balance test

Secondary outcomes

empty

Intervention groups**1****Description**

The first intervention group: In this group, participants will undergo dynamic soft tissue mobilization by an experienced physiotherapist for 4 weeks, three sessions per week. In this group, the patient will take a prone sleeping position, the therapist will be placed on the side of the desired muscle, and the following actions will be performed in sequence. Longitudinal strokes will be applied to the entire hamstring muscle to determine the specific point of muscle tightness. Once the desired point is determined, the rest of the treatment will be limited to this point. The patient will then shift to a supine position and will flex the hip and knee 90 degrees. Deep longitudinal strokes will be applied from the distal to the proximal in the direction of the tight point while the foot will be passively extended. Subsequently the progressive and dynamic technique will be performed. In this technique, the patient will actively extend the leg to activate deep muscle inhibition. In the final stage, the hamstring muscle must be contracted eccentrically by the therapist's hand, despite the resistance created. At this stage, the muscle is stretched to the end of the range of motion. During this movement, 5 deep blows are applied from the distal to the proximal on the tight point.

Category

Other

2**Description**

The second intervention group: In this group, participants will undergo extracorporeal shock wave (ESWT) on hamstring muscles in prone position for 4 weeks, one session per week. The ESWT device is the DUOLITH SD1 model made by STORZ MEDICAL AG. A total of 2,000 impulses will be delivered to the hamstring muscles by the radial head. Of the mentioned impulses, 1,000, 500, and 500 impulses will be for the long head of the biceps femoris, the semitendinosus muscle, and the semimembranosus muscle, respectively. All impulses will enter the middle of these muscles. The repetition frequency of the shock wave will be 15 Hz.
